

# ebmb

## Solve multiband ELIASHBERG equations

---

### Outline

This software provides three programs:

1. `ebmb` itself solves the multiband ELIASHBERG equations (Eqs. 1 or 2) on a cut-off imaginary axis and optionally continues the results to the real axis via PADÉ approximants.  
A material is defined by nothing but an ELIASHBERG spectral function or, as fallback, an EINSTEIN phonon frequency and intra- and interband electron-phonon couplings, COULOMB pseudo-potentials and, if desired, the band densities of BLOCH states, otherwise assumed to be constant.
2. `critical` finds the critical point via the bisection method varying a parameter of choice. Superconductivity is defined by the kernel of the linearized gap equation (Eq. 3) having an eigenvalue greater than or equal to unity.
3. `tc` finds the critical temperature for each band separately via the bisection method. Superconductivity is defined by the order parameter exceeding a certain threshold. Usually, it is preferable to use `critical`.

---

### Installation

The makefile is designed for the *GNU* or *Intel* Fortran compiler:

```
$ make FC=gfortran FFLAGS=-O3
```

---

### I/O

- Parameters are defined on the command line:

```
$ {program} {key 1}={value 1} {key 2}={value 2} ...
```

The available keys and default values are listed in Table 1.

- Unless `tell=false`, the results are printed to standard output.
- Unless `file=None`, a binary output file is created. For `critical` and `tc` it simply contains one or more double precision floating point numbers, for `ebmb` the format defined in Tables 2 and 3 is used.
- The provided *Python* wrapper functions load the results into *NumPy* arrays:

```
import ebmb
results = ebmb.get({program}, {file}, {replace},
                  {key 1}={value 1}, {key 2}={value 2}, ...)
```

`{replace}` decides whether an existing `{file}` is used or overwritten.

Given a band structure, its discretized domain and  $n - 1$  filters, an input file with the density of states resolved for  $n$  subdomains is generated like this:

```
from numpy import cos, dot, linspace, pi
DOSfile('dos.in', epsilon=lambda *k: -cos(k).sum() / 2,
        domain=[linspace(-pi, pi, 1000, endpoint=False)] * 2,
        filters=[lambda *k: pi ** 2 / 2 <= dot(k, k) <= pi ** 2])
```

Let  $\hbar = k_B = 1$ . Fermionic and bosonic MATSUBARA frequencies are defined as  $\omega_n = (2n+1)\pi T$  and  $\nu_n = 2n\pi T$ , respectively. The quantity of interest is the NAMBU self-energy matrix<sup>1</sup>

$$\Sigma_i(n) = i\omega_n[1 - Z_i(n)]\mathbf{1} + \underbrace{Z_i(n)\Delta_i(n)}_{\phi_i(n)}\sigma_1 + \chi_i(n)\sigma_3,$$

where the PAULI matrices are defined as usual and  $i$  is a band index. Renormalization  $Z_i(n)$ , order parameter  $\phi_i(n)$  and energy shift  $\chi_i(n)$  are determined by the ELIASHBERG equations<sup>2</sup>

$$\begin{aligned} Z_i(n) &= 1 + \frac{T}{\omega_n} \sum_j \sum_{m=0}^{N-1} \int_{-\infty}^{\infty} d\varepsilon \frac{n_j(\varepsilon)}{n_j(\mu_0)} \frac{\omega_m Z_j(m)}{\Theta_j(\varepsilon, m)} \Lambda_{ij}^-(n, m), \\ \phi_i(n) &= T \sum_j \sum_{m=0}^{N-1} \int_{-\infty}^{\infty} d\varepsilon \frac{n_j(\varepsilon)}{n_j(\mu_0)} \frac{\phi_j(m)}{\Theta_j(\varepsilon, m)} [\Lambda_{ij}^+(n, m) - U_{ij}^*(m)], \\ \chi_i(n) &= -T \sum_j \sum_{m=0}^{N-1} \int_{-\infty}^{\infty} d\varepsilon \frac{n_j(\varepsilon)}{n_j(\mu_0)} \frac{\varepsilon - \mu + \chi_j(m)}{\Theta_j(\varepsilon, m)} \Lambda_{ij}^+(n, m), \\ \Theta_i(\varepsilon, n) &= [\omega_n Z_i(n)]^2 + \phi_i^2(n) + [\varepsilon - \mu + \chi_i(n)]^2, \end{aligned} \quad (1)$$

and may then be analytically continued to the real-axis by means of PADÉ approximants.<sup>3</sup> The electron-phonon coupling matrices and the rescaled COULOMB pseudo-potential are connected to the corresponding input parameters via

$$\begin{aligned} \Lambda_{ij}^{\pm}(n, m) &= \lambda_{ij}(n - m) \pm \lambda_{ij}(n + m + 1), \quad \lambda_{ij}(n) = \int_0^{\infty} d\omega \frac{2\omega \alpha^2 F_{ij}(\omega)}{\omega^2 + \nu_n^2} \underset{\text{Einstein}}{=} \frac{\lambda_{ij}}{1 + \left[\frac{\nu_n}{\omega_E}\right]^2}, \\ U_{ij}^*(m) &= \begin{cases} 2\mu_{ij}^*(N_C) & \text{for } m < N_C, \\ 0 & \text{otherwise,} \end{cases} \quad \frac{1}{\mu_{ij}^*(N_C)} = \frac{1}{\mu_{ij}^*} + \ln \frac{\omega_E}{\omega_{N_C}} \end{aligned}$$

with the ELIASHBERG spectral function  $\alpha^2 F_{ij}(\omega)$ . Alternatively, if the band density  $n_i(\varepsilon)$  of BLOCH states with energy  $\varepsilon$  per spin, band and unit cell is given,

$$\frac{1}{\mu_{ij}^*(N_C)} = \frac{1}{\mu_{ij}^*} + \ln \frac{2\omega_E}{D} + \frac{1}{\pi} \sum_i \int_{-\infty}^{\infty} d\varepsilon \frac{n_i(\varepsilon)}{n_i(\mu_0)} \begin{cases} \frac{1}{\varepsilon - \mu_0} \arctan \frac{\varepsilon - \mu_0}{\omega_{N_C}} & \text{for } \varepsilon \neq \mu_0, \\ \frac{1}{\omega_{N_C}} & \text{otherwise,} \end{cases}$$

where  $D$  is the electronic bandwidth.  $\mu_0$  and  $\mu$  are the chemical potentials for free and interacting particles, respectively. The latter ensures that the particle number is conserved:

$$2 \sum_i \int_{-\infty}^{\infty} d\varepsilon \frac{n_i(\varepsilon)}{e^{(\varepsilon - \mu_0)/T} + 1} = n_0 \stackrel{!}{=} n \approx 1 - 4T \sum_i \int_{-\infty}^{\infty} d\varepsilon n_i(\varepsilon) \left[ \sum_{n=0}^{N-1} \frac{\varepsilon - \mu + \chi_i(n)}{\Theta_i(\varepsilon, n)} + \frac{\arctan \frac{\varepsilon - \mu}{\omega_N}}{2\pi T} \right].$$

Approximating  $n_i(\varepsilon) \approx n_i(\mu_0)$  yields  $\chi_i(n) = 0$  and the constant-DOS ELIASHBERG equations

$$\begin{aligned} Z_i(n) &= 1 + \frac{\pi T}{\omega_n} \sum_j \sum_{m=0}^{N-1} \frac{\omega_m}{\sqrt{\omega_m^2 + \Delta_j^2(m)}} \Lambda_{ij}^-(n, m), \\ \Delta_i(n) &= \frac{\pi T}{Z(n)} \sum_j \sum_{m=0}^{N-1} \frac{\Delta_j(m)}{\sqrt{\omega_m^2 + \Delta_j^2(m)}} [\Lambda_{ij}^+(n, m) - U_{ij}^*(m)]. \end{aligned} \quad (2)$$

A comprehensive review is given by P. B. ALLEN and B. MITROVIĆ in Solid state physics **37** (1982)

<sup>3</sup>H. J. VIDBERG and J. W. SERENE, J. Low Temp. Phys. **29**, 179 (1977)

At the critical temperature,  $\Delta_i(m)$  is infinitesimal and negligible relative to  $\omega_m$ . This yields

$$\begin{aligned}\Delta_i(n) &= \sum_j \sum_{m=0}^{N-1} K_{ij}(n, m) \Delta_j(m), \\ K_{ij}(n, m) &= \frac{1}{2m+1} [\Lambda_{ij}^+(n, m) - \delta_{ij} \delta_{nm} D_i^N(n) - U_{ij}^*(m)], \\ D_i^N(n) &= \sum_j \sum_{m=0}^{N-1} \Lambda_{ij}^-(n, m) \stackrel{N=\infty}{=} \sum_j \left[ \lambda_{ij} + 2 \sum_{m=1}^n \lambda_{ij}(m) \right].\end{aligned}\tag{3}$$

$Z_i(n)$  is not biased by the cutoff if  $D_i^\infty(n)$  is used in place of  $D_i^N(n)$  in the kernel  $K_{ij}(n, m)$ .

**Table 1:** Input parameters.

- The columns ebmb, tc and critical show which keys are used by these programs.
- The rightmost column indicates which parameters may be chosen as variable for critical. The variable is marked with a negative sign; its absolute value is used as initial guess. If no parameter is negative, the critical temperature is searched for.
- lambda, muStar, and muC expect flattened square matrices of equal size the elements of which are separated by commas. It is impossible to vary more than one element at once.
- dos has lines  $\varepsilon/\text{eV}$   $n_1/\text{a.u.}$   $n_2/\text{a.u.}$  ... with  $\varepsilon$  ascending but not necessarily equidistant.
- a2F has lines  $\omega/\text{meV}$   $\alpha^2 F_{1,1}$   $\alpha^2 F_{2,1}$  ... with  $\omega$  ascending but not necessarily equidistant.

$\langle \text{CHARACTERS key} \rangle : \langle n_1 \times \dots \times n_r \text{ NUMBERS value} \rangle$   
 associate key with value  
 DIM:  $\langle \text{INTEGER } r \rangle \langle r \text{ INTEGERS } n_1 \dots n_r \rangle$   
 define shape (column-major)  
 INT: take NUMBERS as INTEGERS  
 REAL: take NUMBERS as DOUBLES

**Table 2:** Statements allowed in binary output.  
 The data types CHARACTER, INTEGER and DOUBLE  
 take 1, 4 and 8 bytes of storage, respectively.
